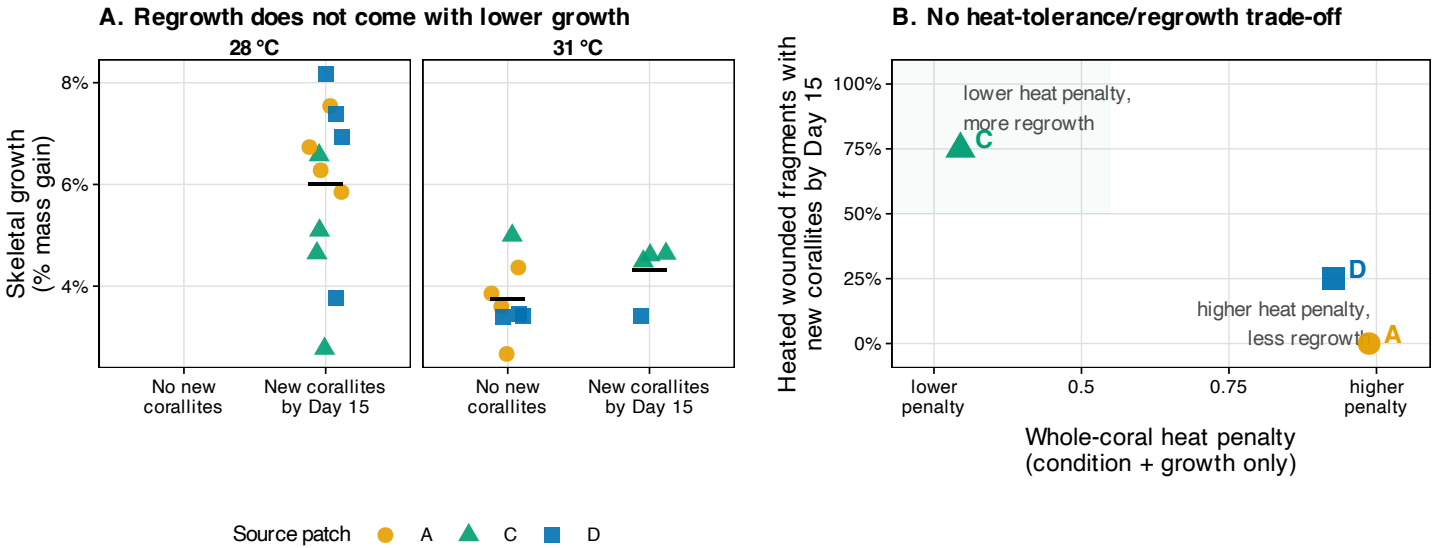
Regeneration trade-off screens

The current data do not show a growth-regeneration or heat-tolerance-regeneration trade-off. Regenerated heated fragments tended to have at least as much growth, and source patch C was both less heat-penalized and more likely to bud new corallites under heat.



Panel A uses wounded fragments with same-fragment growth and Day 15 healing/regrowth scores. Black ticks mark group means. Panel B uses source-patch means; the heat-penalty axis excludes regeneration traits. A, C, and D are source-patch labels, not confirmed genetic individuals.
